

# Restoring and Managing Riparian Areas

*Presentation to the Forest Watershed  
Management Symposium  
12 March 2015 Susanville, CA*

**Themes from the Science  
Synthesis for the Sierra Nevada-  
southern Cascade Range  
and Case Studies from the Arizona  
Mountains**

**Jonathan W. Long ([jwlong@fs.fed.us](mailto:jwlong@fs.fed.us))**

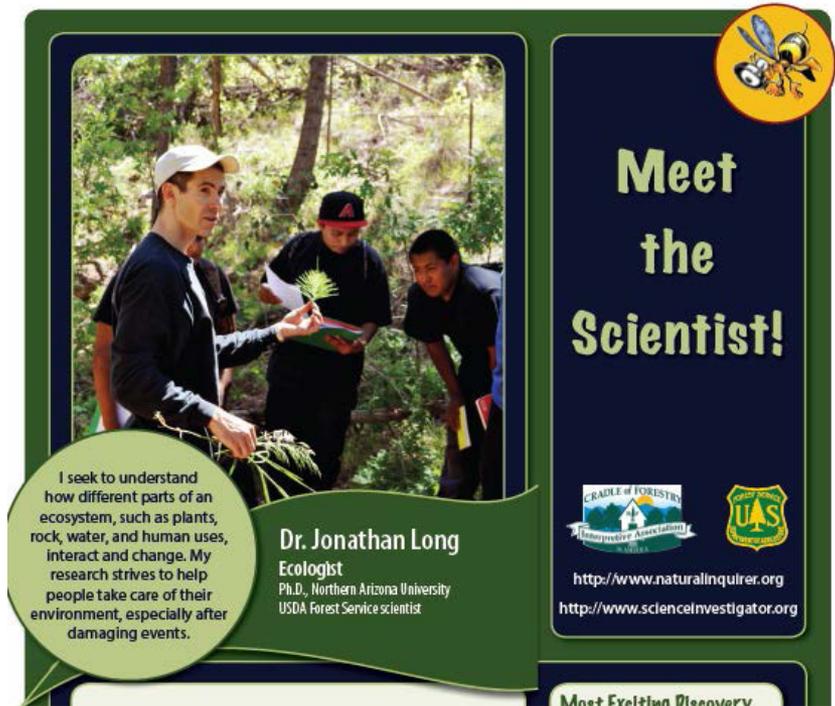

Jonathan Long

**USDA Forest Service, Research & Development**  
*Pacific Southwest Research Station*

# My Background

- Research ecologist with US Forest Service Pacific Southwest Research Station
- Previously with Rocky Mountain Research Station, White Mountain Apache Tribe, and University of Arizona Cooperative Extension
- 20+ years of field research on the White Mountain Apache Reservation in east-central Arizona

I seek to understand how different parts of an ecosystem, such as plants, rock, water, and human uses, interact and change. My research strives to help people take care of their environment, especially after damaging events.

**Dr. Jonathan Long**  
Ecologist  
Ph.D., Northern Arizona University  
USDA Forest Service scientist

**Meet the Scientist!**

# Outline

1. Science synthesis findings relevant to riparian management
2. Conceptual framework and case studies of meadow restoration and post-fire restoration from the White Mountains of Arizona

General Technical  
Report PSW-GTR-247  
(2014)

Jonathan Long

# Key Points

- Intermittent disturbances that kill trees (esp. fires, floods, blowdowns) can rejuvenate systems
- Some systems benefit from physical interventions to reverse degradation
- Some systems respond well to being left alone

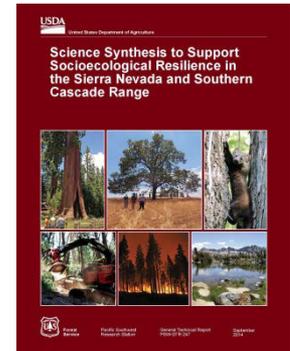

Jonathan Long

# Overall Theme: Promoting Socioecological Resilience

- Addressing stressors facing socioecological systems in an integrated manner
- Reestablishing natural disturbance regimes
- Evaluating effects of landscape-scale, integrated restoration treatments on a range of values, especially water

Jonathan Long

# Chapter 6.1: Strategies for Aquatic & Riparian Ecosystems

- **Restoring fire regimes in upland and riparian forests**
- **Restoring lakes and rivers:**
  - flow regimes below reservoirs
  - maintaining food webs and habitat connectivity
  - Allowing channel migration
- **Restoring wet meadows to maintain hyporheic exchange, flooding, and other key processes**

Carl Skinner

Hat Creek, Reading Fire

# Increased Potential for Extreme Fire Outcomes

Altered Stand Conditions + Wildfires + Climate Change  
→ Expect more extreme fire behavior (e.g., Rim and King fires)

- Much greater risk for high-severity crown fire in untreated scenarios than in fuels-treated scenarios (Chapter 4.1)

Corral Creek after Rim Fire

# Risks of Wildfires to Aquatic Systems

- Reports of isolated, but large debris flows in the Sierra Nevada  
→ could they become more frequent under more variable storm events?

Jerry DeGraff

Post-fire debris flow on Oak Creek  
on east side of Sierra Nevada

# Chapter 1.1: Restoring Fire as an Essential Watershed Process

- Rejuvenation of riparian and aquatic habitats by fire is ecologically important
- However, systems that are already degraded conditions or have limited connectivity for aquatic life may be vulnerable

The managed Lion fire burned watersheds occupied by California golden trout

Brent Skaggs

# Metrics for Evaluating Fire Effects

- Size of high severity patches
- For aquatic systems, percent of watershed burned at high (or high-moderate) severity may be useful indicator

Watershed in Arizona burned at 100% high severity (using BAER criteria), resulted in extensive channel erosion

# Chapter 1.3: Restoring Process and Heterogeneity Using Fire + Harvesting Treatments

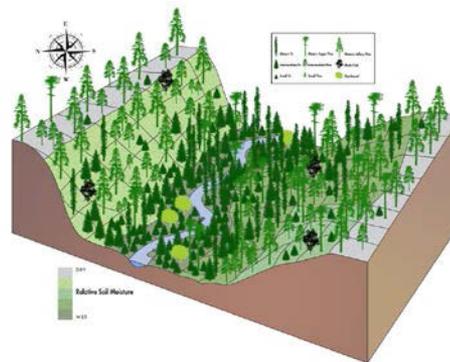

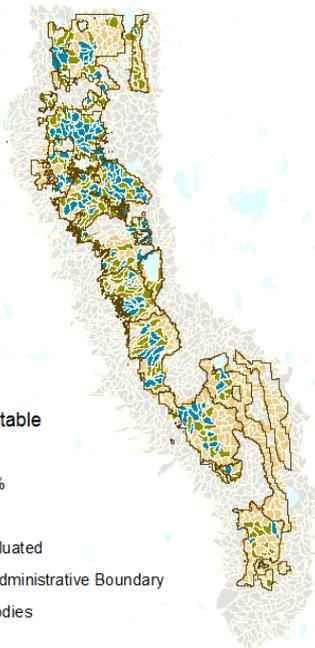

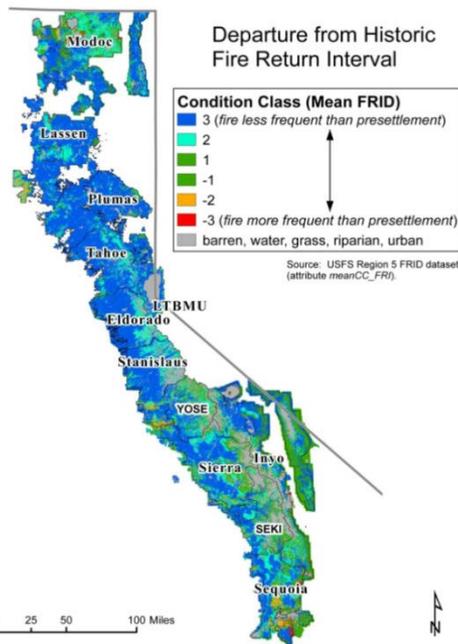

Fire regime

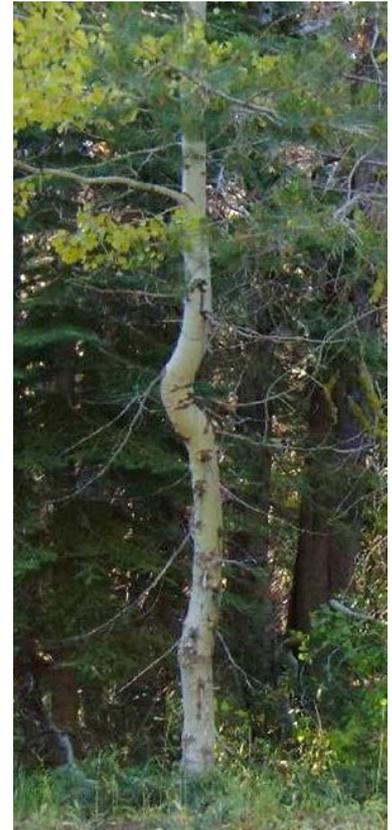

Suitability for treatment

→ Consider ecological and social factors at multiple scales

# Use More Intense Prescribed Fires?

- Typical prescribed fires have often been very light—higher intensity fire in riparian areas may be needed to restore aspen (Krasnow et al. 2012)
- Given limitations on mechanical harvest in many areas, prescribed fire may be important for reshaping forest structure in many areas

# Chapter 6.2: Riparian Forest Management

- Recognize the distinctive characteristics of riparian areas in different regions

# Guidelines from Wet Pacific Northwest Forests do not translate well to drier, more fire-dominated systems

## Down logs for wildlife

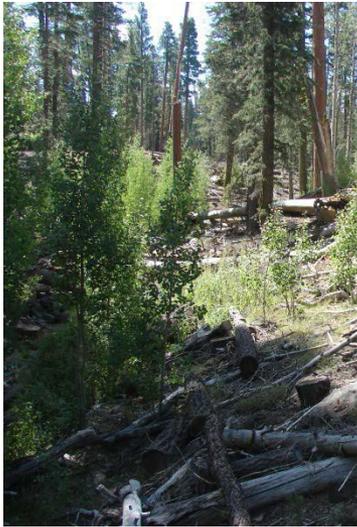

Accumulations of smaller-sized coarse woody debris due to lack of fire (Knapp 2015) may not be good for small mammals (Sollman et al. in press)

## In-stream woody debris

Large woody debris “played a relatively minor role” in channel morphology on the Stanislaus NF, in part due to faster decay (Ruediger and Ward 1996)

## Shade

Consider possible benefits (for amphibians and fishes) from reducing shade (PSW-GTR-247 and PSW-GTR-244)

Jonathan Long

# Riparian Forest Restoration

- Plan for heterogeneity based on reference disturbance regimes and landscape attributes
- Do not expect “simple, effective, standardized prescriptions, formulas, or procedures” for attributes such as large woody debris (PSW-GTR-181)
- Consider treatments especially in areas at risk for high-severity fires

# Chapter 4.3: Post-fire Management

Riparian areas are generally **resilient** to wildfire, but there are special concerns:

- **Hydrologic effects of high soil burn severity**
- **Long-term productivity and resiliency of riparian habitats**
  - Can grow large trees and provide sources of large woody debris
  - Wildlife habitat and corridors
  - Climate change refugia

# Salvage in Riparian Areas

*“Without a commitment to monitor management experiments, the effects of postfire riparian logging will remain **unknown and highly contentious**”*

– Reeves et al. 2006, “Postfire Logging in Riparian Areas”

- However, there are reasons to consider salvage in these areas
- Consider removing the trees that you would have removed before the fire to restore structure and fire resilience

# Chapter 1.6: Adaptive Management

Need combinations of experiments, large demonstration areas, long-term monitoring following large fires, and modeling

- A. Evaluate active management for riparian and wildlife zones
- B. Evaluate phased treatments to reestablish fire regime
- C. Evaluate impacts to water resources and other socioeconomic values following large or multiple fires

Experimental forests and watersheds

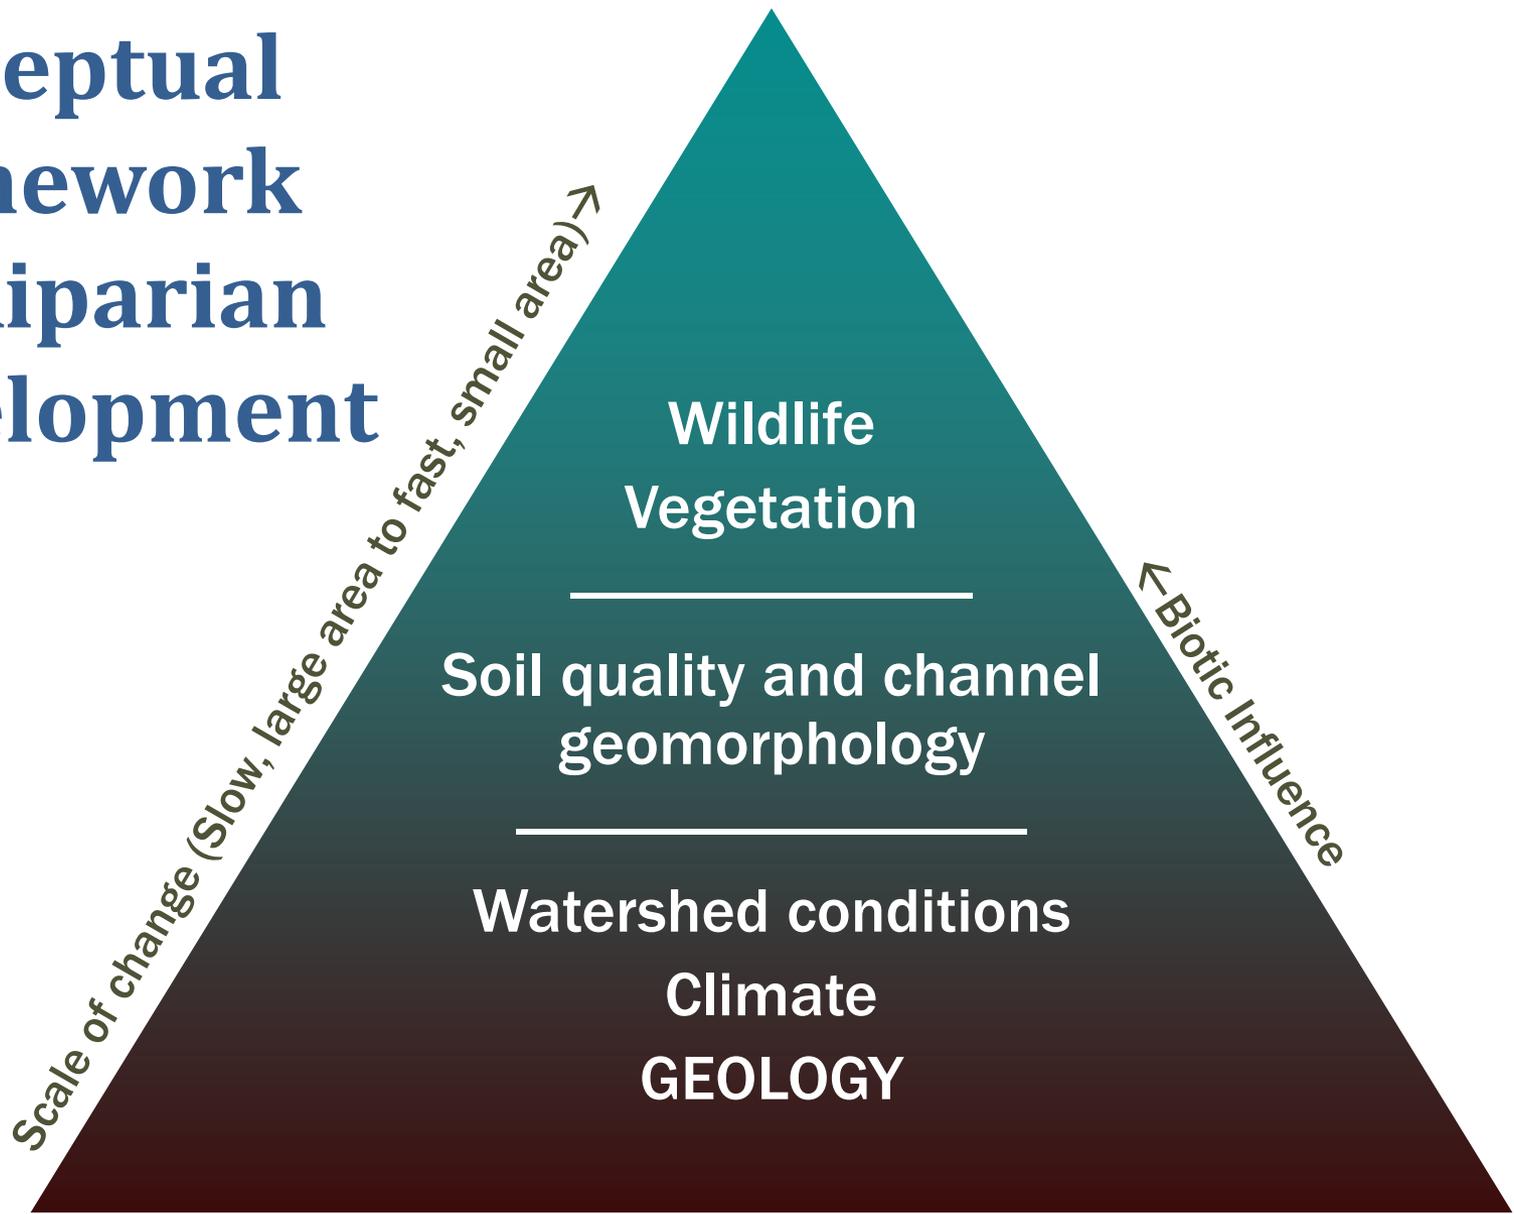

Post-fire studies

# CONCEPTUAL FRAMEWORK FOR RIPARIAN RESTORATION AND CASE STUDIES FROM THE WHITE MOUNTAINS OF ARIZONA

1. Conceptual framework
2. Meadow incision and restoration, including Alder encroachment
3. Post-fire incision and restoration

# Conceptual Framework for Riparian Development

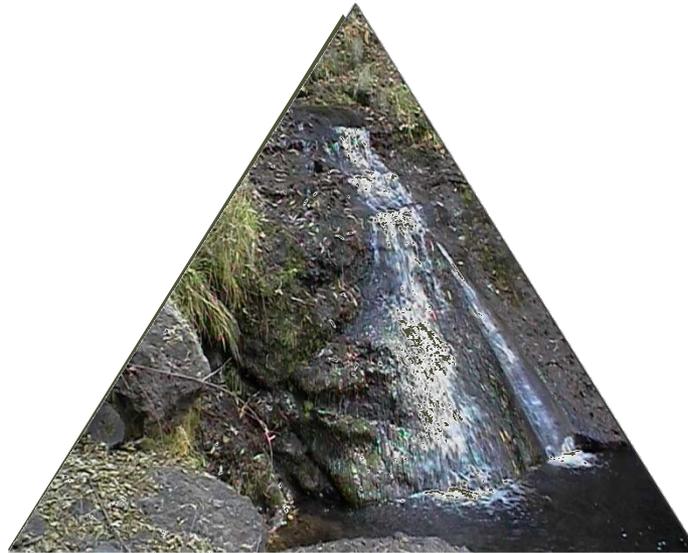

# GEOLOGY

controls key processes of riparian development that are fundamental for restoration potential

Sediment supply

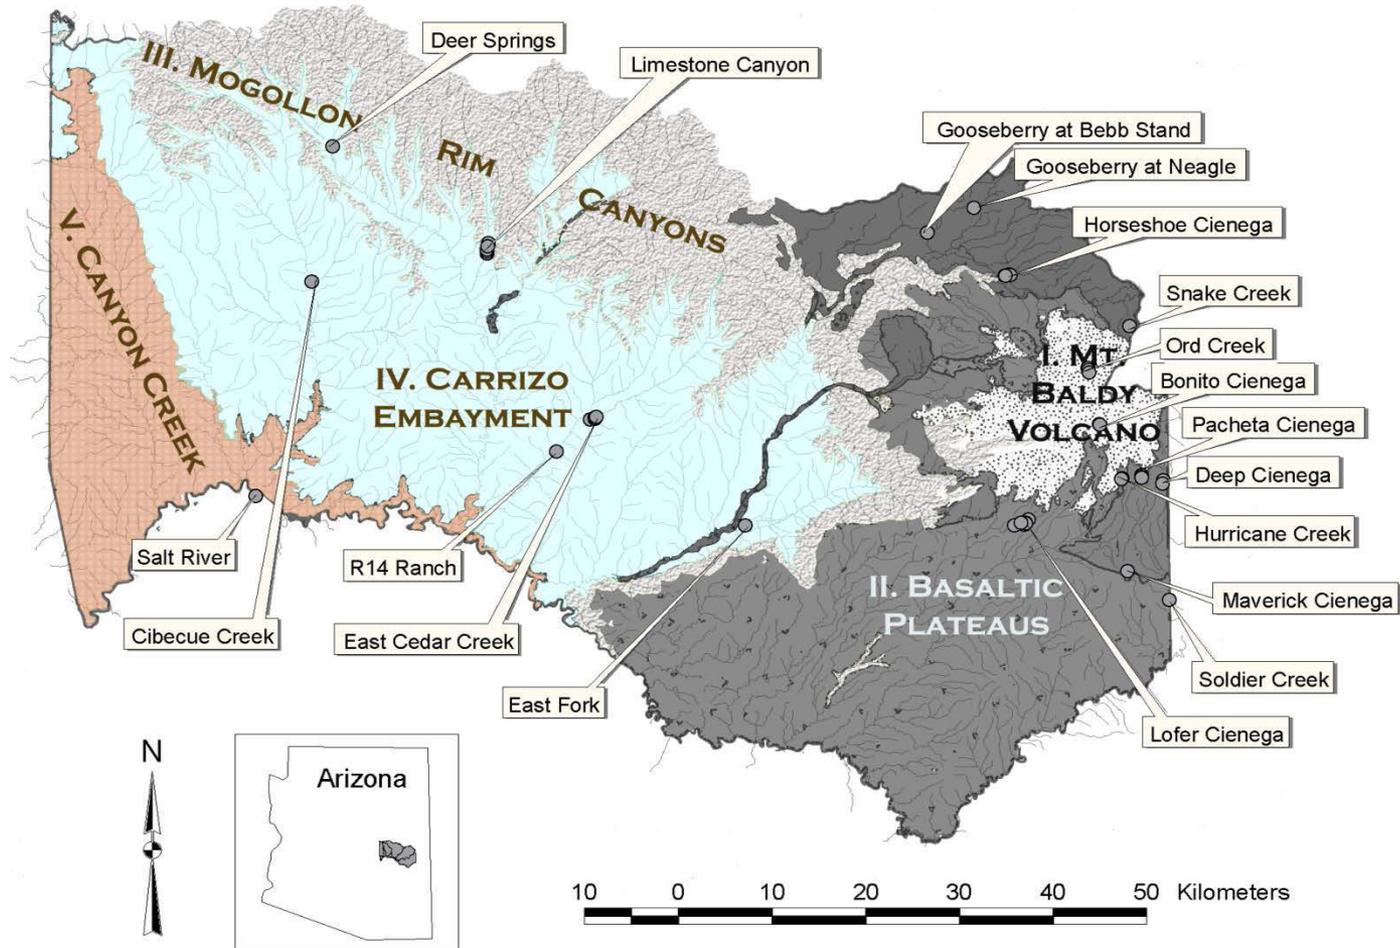

Channel morphology

Vegetative development

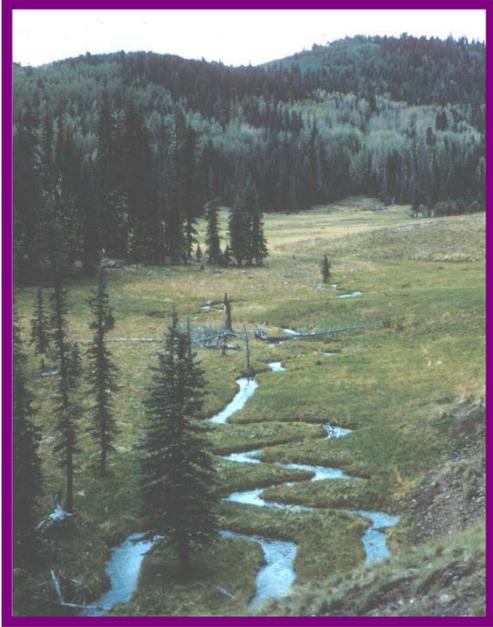

# Ecological Context: White Mountain Apache Reservation

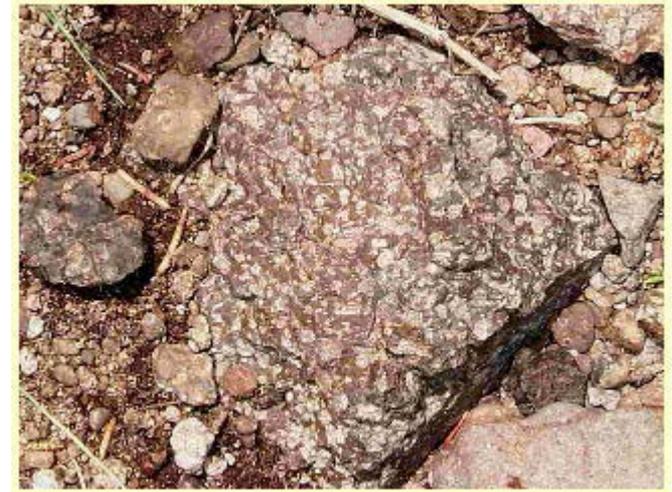

<b>Dominant Lithotypes</b>	<b>Texture</b>	
	<b>Coarse</b>	<b>Fine</b>
<b>Volcanic</b>	<b>I. Felsic volcanics</b> 	<b>II. Mafic volcanics</b> 
<b>Sedimentary</b>	<b>III. Sandstone</b> 	<b>IV. Siltstone</b> 

# I. Felsic Volcanics

Productive and  
Stable

Coarse bed  
materials  
promote  
stability

Meadows formed in  
glacial and pseudo-  
glacial deposits

Most  
productive  
trout  
habitat

# Ord Creek: Very high trout biomass

# II. Basaltic Volcanics

- Fine-textured soils vulnerable to degradation

- Lack of coarse substrates limits fish habitat and slows recovery

# III. Coarse Sedimentary Areas

- Lack fine substrates
- Often slow to recover
- Impacted by severe post-fire floods

# IV. Fine Sedimentary Areas

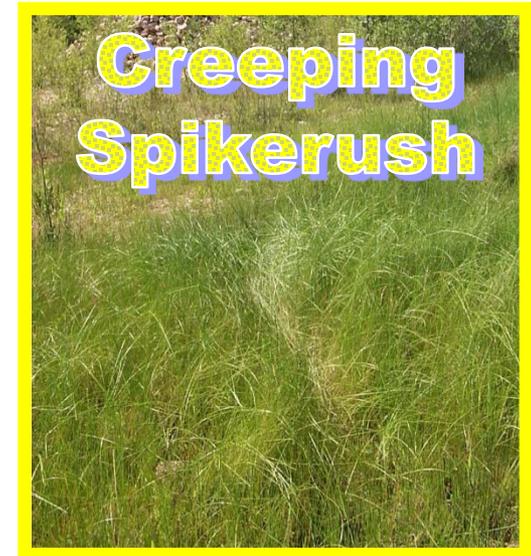

- Large watershed areas with high production of fine sediments
- Vulnerable to lateral erosion
- But can reform quickly with water + sediment + vegetation growth

# Grass-like plants: keys to wetland recovery

Different species are important in different ecoregions, but cord-like roots and dense leaves to trap sediments are consistently important

# MEADOW RESTORATION CASE STUDIES

Using “active” and “passive restoration”

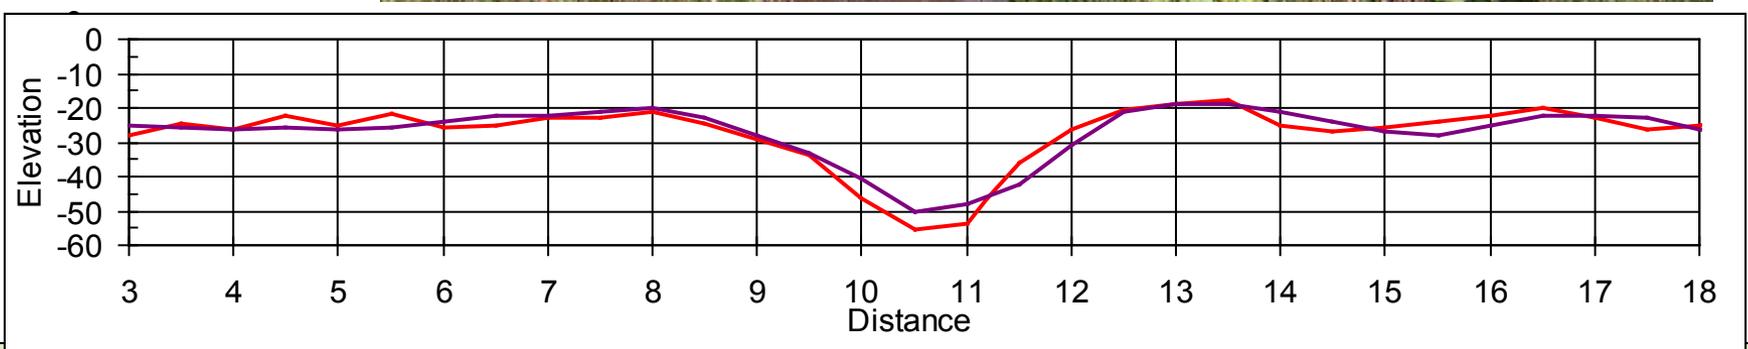

Pacific Southwest Research Station

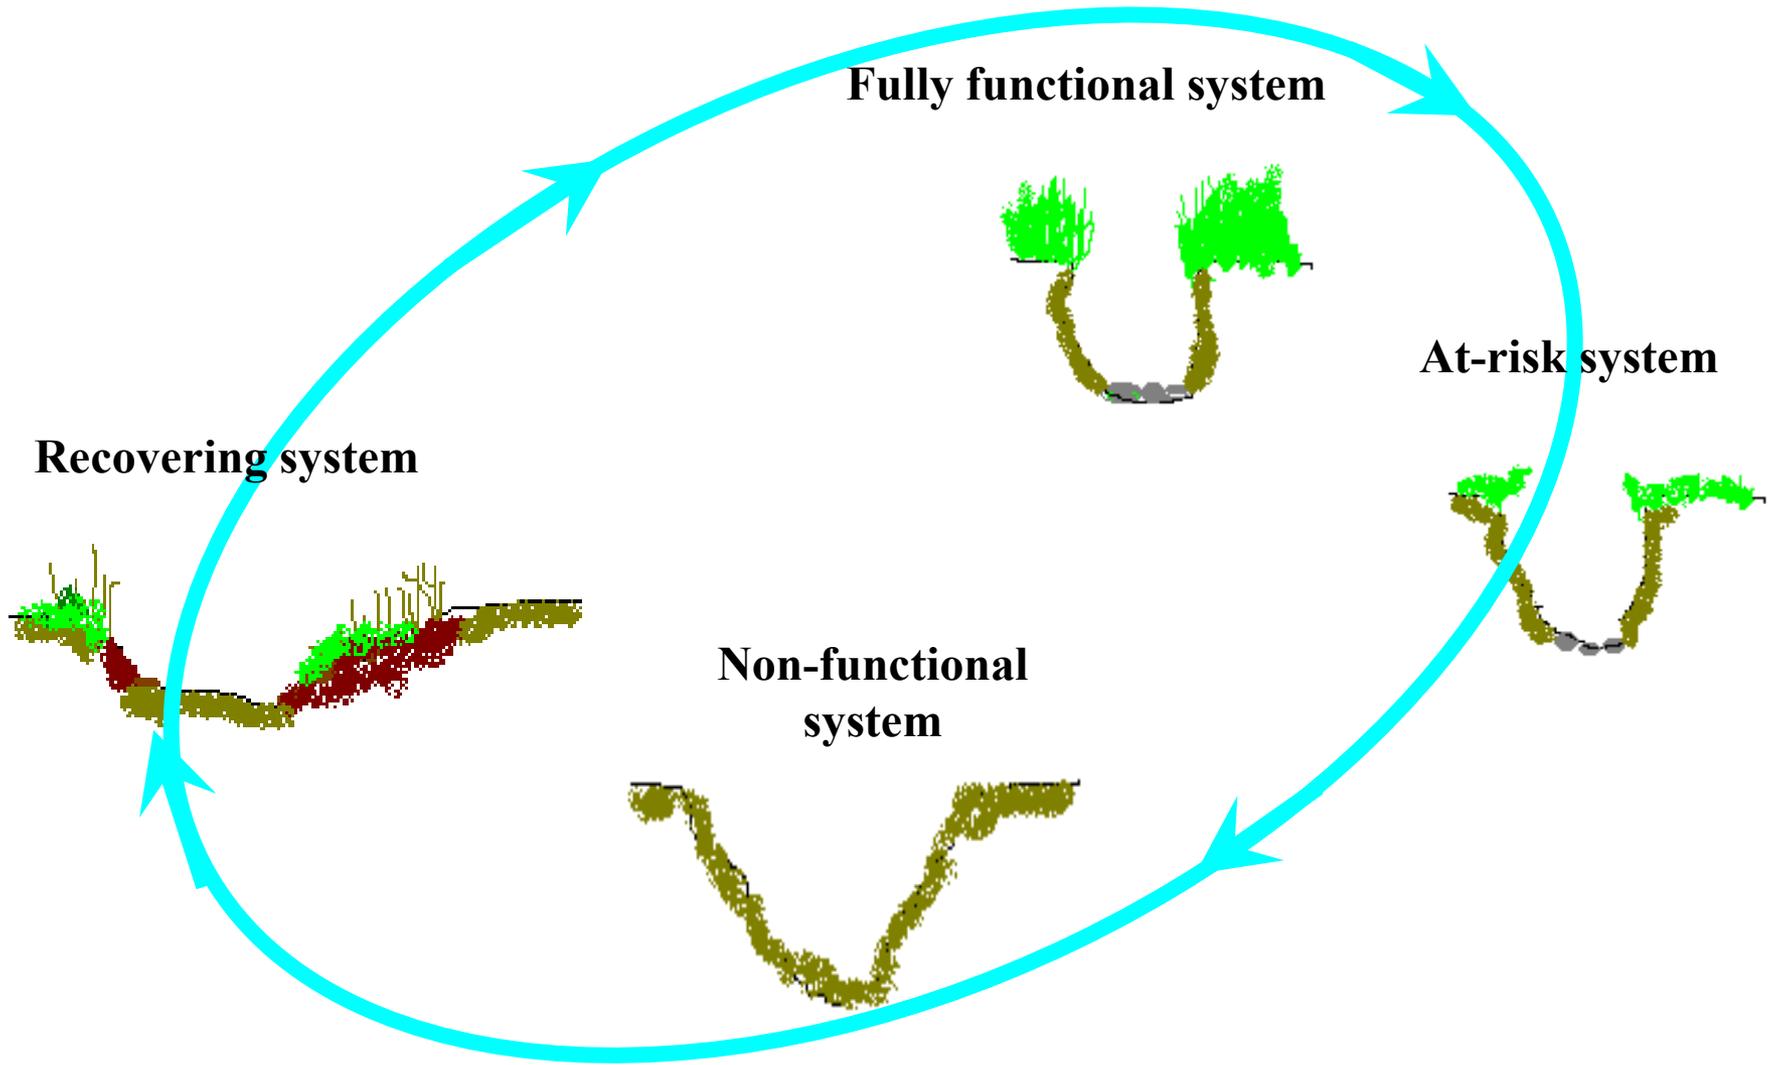

# Process of Channel Degradation

Native trout  
residing in scour  
pools

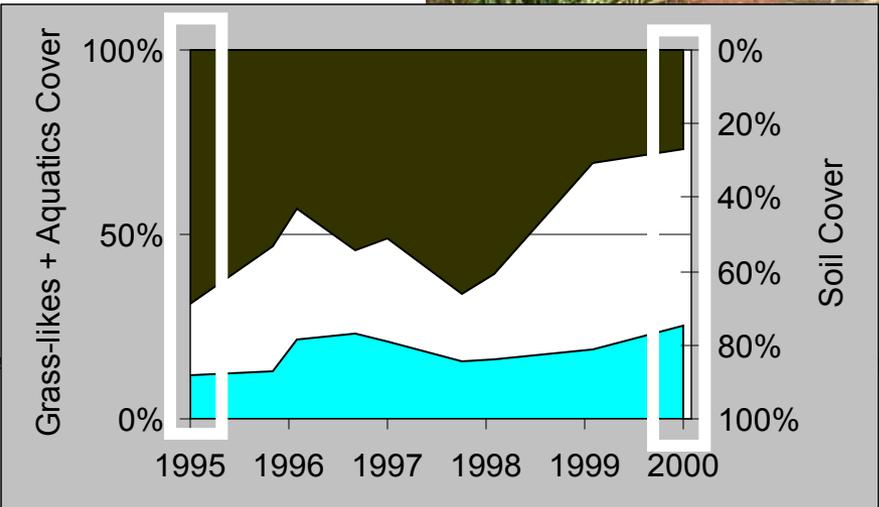

# Recovery Process

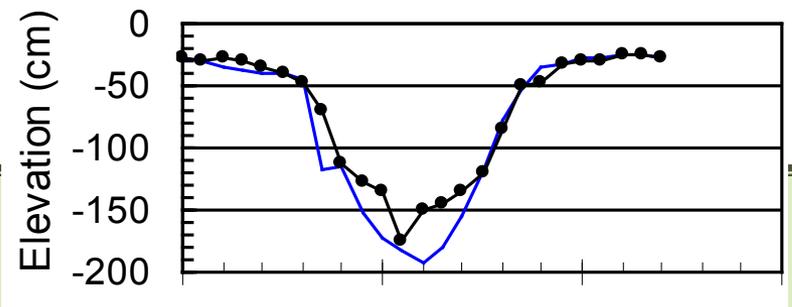

# Recovery

Reduction of bare soil

Aggradation

# Riffle Formation Treatments

1. Controlling grazing impacts
2. Placing mixtures of gravels and cobbles
3. Transplanting sedges

Detailed in Medina and Long (2004)  
“Placing riffle formations to restore  
stream functions in a wet meadow.”  
Ecological Restoration.

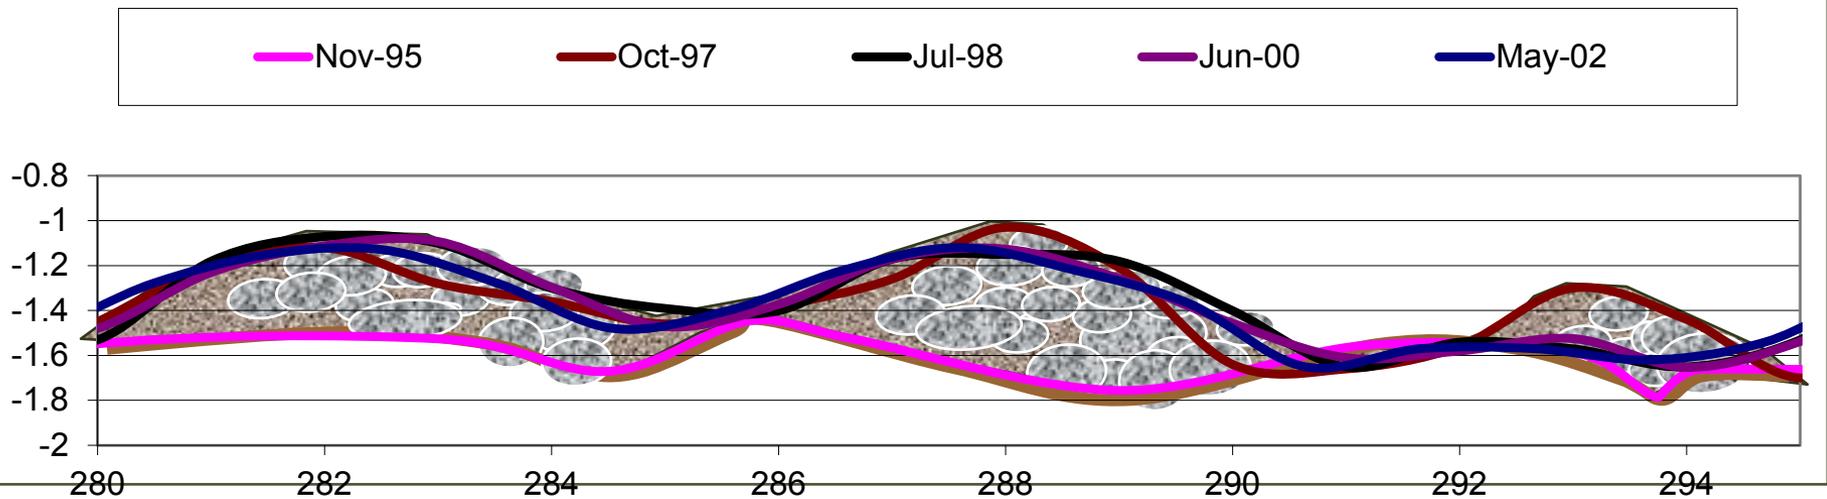

# Effects on Channel Morphology

- Increase bedform amplitude
- Rearmor bed with coarse substrates

→ Increased roughness

→ Reduced erosion potential

# Effects on Water Level

# Reestablishing Formative Processes

1. Pool-riffle development
2. Overbank flooding
3. **Fine sediment deposition**
4. **Vegetative growth**
5. Water table rise
6. Channel armoring

Vegetative growth on bars and riffles

# Effects on Bed Substrates

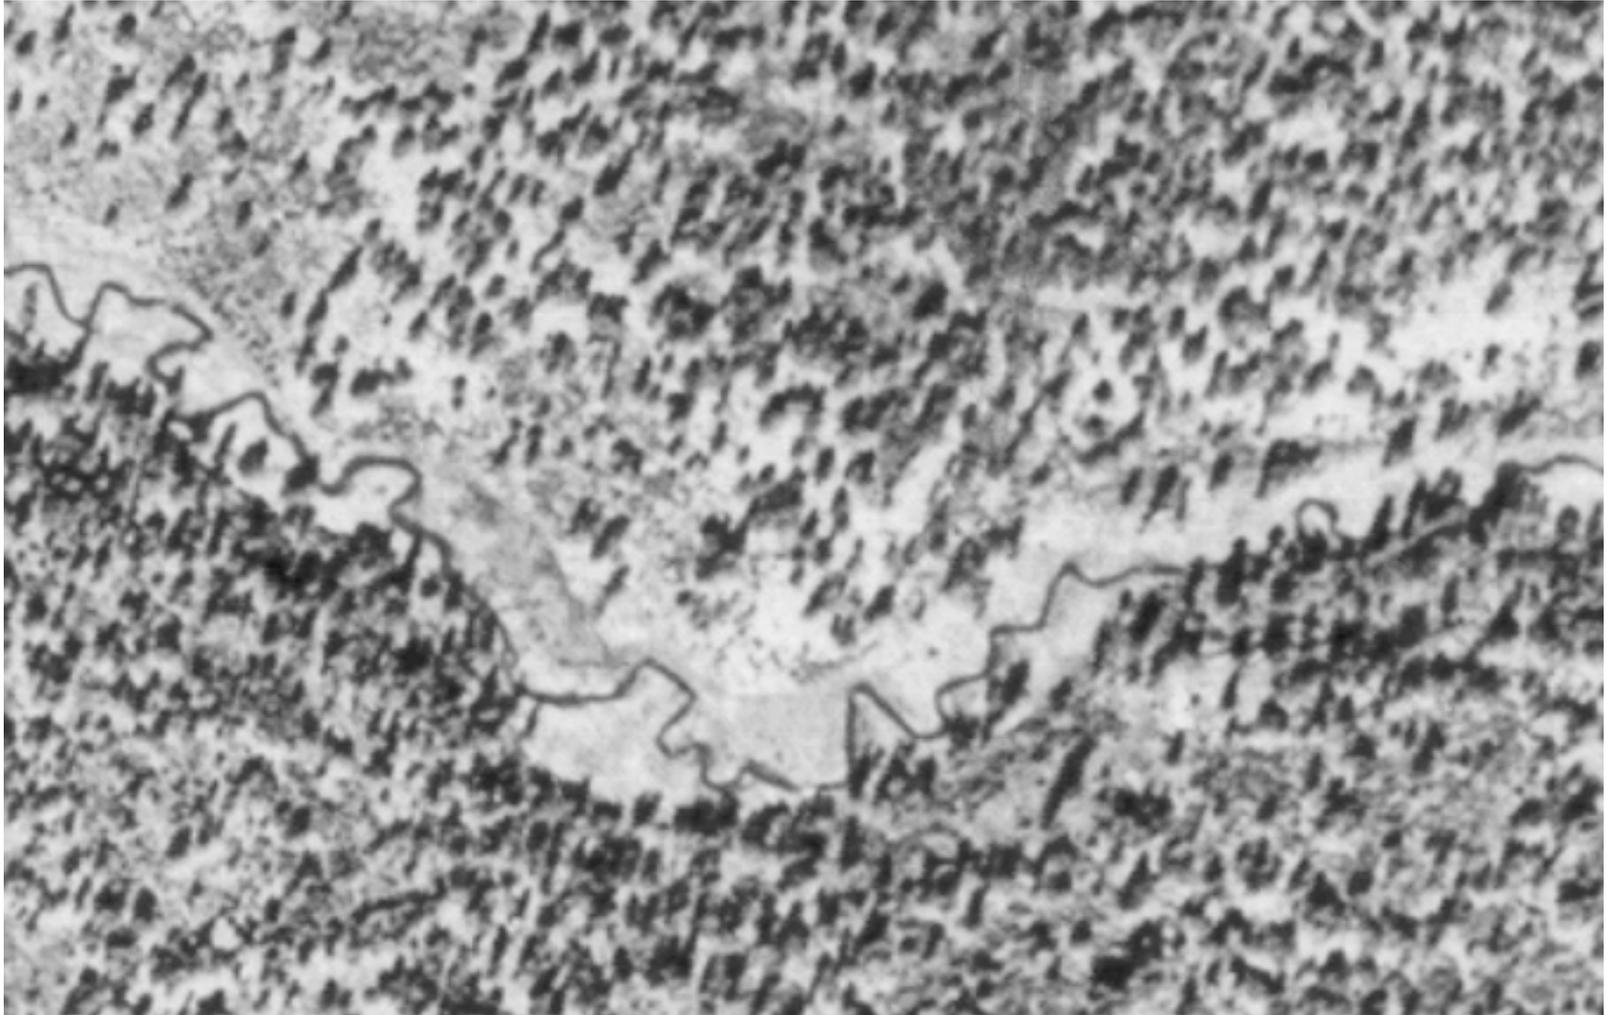

# Thinleaf Alder Dynamics

- Common in steeper non-meadow reaches, but encroaches into degraded meadows
- Cycle of growth and dieback

# Centerfire Creek, AZ 1935

Open  
ponderosa  
pine stands  
and

meadow

Pacific Southwest Research Station

# Centerfire Creek, AZ 1968

Channel  
incision and  
a new road

# Centerfire Creek, AZ 1993

Alders now  
line most of  
the channel

**Pacific Southwest Research Station**

If necessary input Secondary Office here

# Boggy Creek 1950

Meadow  
dominated  
by  
herbaceous  
vegetation  
and widely  
spaced Bebb  
willow

# Boggy Creek, AZ 1993

Encroachment  
of alder along  
the channel

Pacific Southwest Research Station

# Boggy Creek exclosure (Station 7) July 1993

# Boggy Creek enclosure (Station 7) July 1996

# Boggy Creek enclosure (Station 7) July 1998

**Pacific Southwest Research Station**

If necessary input Secondary Office here

# Thinleaf Alder Dynamics

- Forms weak debris dams that appear to facilitate channel widening

# POST-FIRE CASE STUDIES

## When to intervene in channels?

**“A growing body of literature is discouraging further interference in natural landscape disturbance processes, such as fire and post-fire erosion, because the dynamic response to such disturbances may help maintain more diverse ecosystems that are more resilient to changed climates” (Goode et al. 2012)**

# Passive Restoration + Fire-Induced Sediment Deposition

# Take Home Points

- Understand how geology and disturbances influence site development

- Restoration depends on reestablishing key processes often, but not always, through structural interventions and managing woody vegetation
